ABSTRACT

BACKGROUND: Benign multicystic peritoneal mesothelioma (BMPM) is a rare intra-abdominal tumor. Although considered by many to be benign, this tumor has a high local recurrence rate. Because of its rarity, preoperative diagnosis is difficult and its origin and pathogenesis are uncertain. There are no evidence-based treatment strategies for BMPM. It is agreed that the best treatment strategy for BMPM is en bloc removal, which can avoid recurrence. An increasing body of evidence supports a pivotal role of the cytoplasmic serine/threonine kinase mTOR in the development and progression of several neoplastic diseases and specific mTOR inhibitors, including rapamycin, have been suggested as potential therapeutic options for different cancers.

CASE PRESENTATION: A 65-year-old male with end stage renal disease on hemodialysis for 7 years presented with BMPM. He underwent surgery to remove multiple peritoneal cysts, but 4 months later he experienced a recurrence of the disease. Since immunohistochemistry of the cysts demonstrated a high level of phosphorylation of p70S6 kinase, a downstream mTOR target. On these bases, a target therapy that block PI3K/Akt/mTOR pathway have a scientific and logical base to treat this rare intra-abdominal neoplasia. Then low dose rapamycin therapy was started. Long-term mTOR inhibition resulted in a complete and stable remission of BMPM.

CONCLUSIONS: The current case is the first report of BMPM successfully treated with rapamycin and with a long-lasting response to mTOR inhibition.

KEY WORDS: Benign multicystic peritoneal mesothelioma; Treatment; mTOR; Rapamycin
BACKGROUND

Mennemeyer and Smith [1] first described benign multicystic peritoneal mesothelioma (BMPM) in 1979. Although usually considered benign, this tumor has a high rate of local recurrence [2]. Clinical presentation depends on the size and location of the cysts, and is usually represented by abdominal tenderness, dyspareunia, constipation, urinary symptoms and the detection of a palpable abdominal mass. The etiology and pathogenesis are still largely unclear [3-5]. Indeed, it is still a matter of debate whether BMPM is a neoplastic disease or a reactive process [6]. Although en bloc removal of the cysts is considered the best therapeutic approach, the rate of recurrence after complete resection is higher than 50% [2]. In consideration of its benign nature, adjuvant chemotherapy and/or radiotherapy are not currently indicated for patients with BMPM. Other treatments including hormone therapy, sclerotherapy, and thermotherapy no provide any beneficial effect.

Mammalian target of rapamycin (mTOR), a cytoplasmic serine-threonine kinase, is a key molecular switch of protein translation and cell cycle progression [7]. An increasing body of evidence suggests that this kinase may play a pivotal role in the development and progression of several neoplastic diseases [8]. Guo et al recently demonstrated that intra-peritoneal injection in mice of Cre adenovirus with conditional alleles of TSC1 leads to the constitutive activation of mTOR and development of mesothelioma [9]. In addition, they demonstrated that more than 60% of human mesotheliomas are characterized by mTOR activation [9]. On the other hand, the efficacy of mTOR inhibition has been clearly demonstrated in several malignancies and in cystic diseases [10-12].
CASE PRESENTATION

We describe the case of a 65-year-old male with end stage renal disease on hemodialysis for 7 years that suffered significant weight loss (20 Kg) over six months and a marked increase in abdominal girth. A CT scan performed on January 2011 showed abundant ascites and a right pleural effusion, excluding neoplastic lesions of lungs, liver, pancreas and bowel. The patient underwent a paracentesis that did not demonstrate any cytological or microbiological alterations. In consideration of these findings, he underwent an intensive, daily, hemodialysis program without benefit.

He presented at our Division in April 2011 in poor clinical conditions with an advanced cachectic status and abundant ascites with diffuse abdominal distension and tenderness. HCV and HBV serology was negative. A new CT scan demonstrated “a voluminous peritoneal fluid cyst extending from the diaphragm to the pelvis, displacing stomach, liver and bowel” (Figure 1A-B). Moreover, under ultrasonographic guide, we collected a sample of the cyst fluid. Microbiological and cytological tests resulted negative.

Based on these findings the patient underwent an explorative laparotomy. Intraoperative examination showed a diffuse peritoneal thickening with one major and several minor cystic lesions. At this point, we hypothesized a diagnosis of BMPM. Then, we removed the multiple cystic peritoneal formations. The histological and immunohistochemical evaluation of the peritoneal cysts showed a positivity for mesothelial cells markers and for calretinin and confirmed the clinical hypothesis.

Four months after surgery the patient presented with abdominal pain. A new CT scan demonstrated the presence of a new voluminous peritoneal cyst (Figure 1C). The patient refused a further laparotomy. Based on our findings of a significant phosphorylation of p70S6 kinase, a downstream target of mTOR, in the mesothelial cells obtained from the cyst fluid, (Figure 2), and of the existing literature [9-12], after our Institutional review board approved and once obtained a written informed consent from patient, we began a rapamycin treatment cycle. We administered the drug at an initial loading dose of 3 mg for the first day, and at a maintenance dose of 1 mg/day to obtain a blood through level of 3-5 ng/ml. After six months of rapamycin therapy, we observed the cyst volume reduction and the abdominal pain disappeared (Figure 1D). The patient continued to take low rapamycin doses (0.5 mg day obtaining a mean blood trough level of 3.1±0.4 ng/ml) and at the CT scan, performed after two years of treatment, the cyst completely disappeared (Figure 1E-F). During the completely follow period, rapamycin was well tolerated and the patient did not present side effects.
DISCUSSION

BMPM is a rare disease, characterized by a controversial pathogenesis. Some authors consider BMPM as a localized, benign neoplastic lesion arising from the mesothelial cells [2]. The hypothesis of a neoplastic origin is based on the slow, but progressive growth of the lesions, the tendency to recur after surgical resection, and the high disease related mortality in advanced stages [13, 14]. On the other hand, a second hypothesis suggests that the underlying cause of BMPM might be represented by a diffuse chronic peritoneal inflammation leading to the proliferation and migration of mesothelial cells and the subsequent formation of the cystic lesions.

In our case, we demonstrated an increased phosphorylation of p70S6 kinase, a downstream target of mTOR, in mesothelial cells of the cystic lesions. This cellular event has been often used a reliable marker of mTOR activation and has been suggested as a potential pharmacodynamic target to monitor the efficacy of mTOR inhibition. Our observation of a hyper-phosphorylation of p70S6 kinase in the cells obtained by the BMPM cysts may support the neoplastic hypothesis suggesting an activation of mesothelial cells resembling the one observed in mesothelioma. In addition, the observation of a prompt and stable response to rapamycin treatment clearly suggest a key role for mTOR in the pathogenesis of the disease and further supports the hypothesis of a neoplastic nature of BMPM. Indeed, the PI3K/Akt/mTOR pathway has been shown to play a role in the development and progression of several neoplastic diseases [15, 16]. mTOR sits at an intersection of several inputs to the cell, integrating signals from both growth factors and nutrients and mediating its effects through two main effectors, p70S6 kinase and 4E-BP1/eIF4E, with a well-defined role in the regulation of protein translation [15-17]. The mTOR pathway can, indeed, promote neoplastic cell survival and proliferation through the phosphorylation and sequestration of the pro-apoptotic Bad [18], up-regulation of FLIPs [19], translation of anti-apoptotic proteins, and support of the mitochondrial energy production [15,20,21]. Thus, great interest has arisen in the potential benefits of mTOR inhibition in tumors [16, 17]. In an interesting and elegant study, Wilson et al. suggested that mTOR was the key effector of mesothelioma cells survival, suggesting a therapeutic role for mTOR inhibition in mesothelioma [22]. Altomare et al. [23] reported that 65% their cases of mesothelioma were characterized by an elevated phosphorylation and subsequent activation of AKT, the serine kinase upstream of mTOR in the signaling cascade. In addition, they demonstrated for the first time a homozygous deletion of PTEN in one of their patients [23]. Zhou et al [24] reported the activation of the PI3K/AKT/p70S6K pathways in mesothelioma, but not in non-neoplastic mesothelial cells. AKT activation was directly related to the coordinated activation of receptor tyrosine kinase EGFR, MET, and AXL. In addition, the inhibition of the mTOR pathway obtained the same anti-proliferative effect observed by the concurrent inhibition of EGFR, MET,
and AXL. Dual targeting of PI3K/mTOR by a combination of everolimus, a specific mTOR inhibitor, and AKT knockdown had a greater effect on mesothelioma proliferation and viability than inhibition of individual activated RTKs or downstream signaling intermediates [24]. Finally, Guo et al [9] clearly demonstrated that constitutive mTOR activation in mesothelial cells, induced by TSC deletion, induces the development of mesothelioma in mice.

Interestingly, several studies clearly suggest that the anti-neoplastic effect of mTOR might be, at least partially, due to its well-known anti-angiogenic action [10, 25]. Since in BMPM lesions we did not observe any sign of neoangiogenesis (data not shown), it is unlikely that the beneficial effects of mTOR inhibition that we observed was correlated with the anti-angiogenic effect of rapamycin, further supporting the hypothesis of a direct effect on mesothelial cell of the cysts. Since we do not have any reliable information on the pathogenesis of cyst formation in this particular setting we cannot conclude whether the results on cysts’ growth induced by mTOR inhibition might be linked only to the inhibition of mesothelial cells proliferation or to a specific effect of this signaling pathway on cell polarity and secretion demonstrated in other settings [12,26].

Interestingly, the dose of rapamycin used is extremely low when compared to the immunosuppressive doses currently employed for kidney transplantation. This observation might explain the lacking of infections and side effects often observed in the transplant setting.

CONCLUSIONS

In conclusion, based on knowledge that mTOR pathway is activated in several malignancies and on our previous positive experiences with mTOR inhibition in cystic diseases, the use of rapamycin could be a logical option for the treatment of BMPM. Our report is the first case of BMPM successfully treated with rapamycin with a long-lasting response to mTOR inhibition. This observation opens new opportunities in the therapy of this rare abdominal neoplasia characterized by a difficult management.
